AAZ65654 to AAZ69578 represent human biallelic markers from the present invention, which contain a polymorphic base at position 24 of their nucleotide sequences. AAZ69579 to AAZ7440 represent amplification primers for the biallelic markers. The biallelic markers of the invention bave a variety of uses: they can be used for high density mapping of the human genome, and in complex association studies and haplotyping studies which are useful in determining the genetic basis for disease states. Compositions and methods of the invention can also be useful for the identification of the targets for the development of pharmaceutical agents and diagnostic methods, as well as the characterisation of the pharmaceutical ascentical agents acting on a disease as well as other treatment. N.B. The SEQ ID NOS 2852, 2913, 2974, 3035, 3056, 3157, 3227, 3297 and 3367, are not actually given a sequence in the Sequence Listing from the
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Human, variant thrombospondin 1, variant thrombospondin 4; SNP;

The present invention provides a method of diagnosing a vascular disease in an individual, involving determining the sequence at various oblymorphic sites within the human thrombospondin 1 and thrombospondin 4 genes. The sequences at a number of polymorphic sites are also provided in the specification. In particular the method can be used in the diagnosis of athersocherosis, myocardial infarction, coronary heart disease, stroke, peripheral vascular diseases, venous thromboembolism and pulmonary embolism. Single nucleotide polymorphisms (SNDs) are also correlations to diseases. The present sequence is an example of one of the human gene SNPS shown in the specification
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Human; variant thrombospondin 1; variant thrombospondin 4; SNP; polymorphism; vascular disease; coronary artery disease; forensics; myocardial infarction; atherosclerosis; stroke; venous thromboembolism; pulmonary embolism; paternity test; ds.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Nucleic acids comprising single nucleotide polymorphisms, useful in applications such as forensics, paternity testing, medicine, genetic analysis and phenotype correlations to diseases such as diabetes and

The present invention provides a method of diagnosing a vascular disease in an individual, involving determining the sequence at various oblymorphic sites within the human thrombospondin 1 and thrombospondin 4 genes. The sequences at a number of polymorphic sites are also provided in the specification. In particular, the method can be used in the diagnosis of atherosclerosis, myocardial infarction, coronary heat disease, stroke, peripheral vascular diseases, venous thromboembolism and pulmonary embolism. Single nucleotide polymorphisms (SNPs) are also correlations to diseases. The present sequence is an example of one of the human gene SNPS shown in the specification
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Human; variant thrombospondin 1; variant thrombospondin 4; SNP;

The present invention provides a method of diagnosing a vascular disease in an individual, involving determining the sequence at various polymorphic sites within the human thrombospondin 1 and thrombospondin 4 genes. The sequences at a number of polymorphic sites are also provided in the specification. In particular, the method can be used in the diagnosis of atherosis, myocardial infarction, coronary heart disease, stroke, peripheral vascular diseases, venous thromboembolism and pulmonary embolism. Single nucleotide polymorphisms (SNPs) are also correlations to diseases. The present sequence is an example of one of the human gene SNPS shown in the specification
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                The present invention provides a method of diagnosing a vascular disease in an individual, involving determining the sequence at various polymorphic sites within the human thrombospondin 1 and thrombospondin 4 genes. The sequences at a number of polymorphic sites are also provided
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Human; variant thrombospondin 1; variant thrombospondin 4; SNP; polymorphism; vascular disease; coronary artery disease; forensics; myocardial infarction; atherosclerosis; stroke; venous thromboembolism; pulmonary embolism; paternity test; ds.

in the specification. In particular, the method can be used in the diagnosis of atherosclerosis, myocardial infarction, coronary heart disease, stroke, peripheral vascular diseases, venous thromboembolism and pulmonary embolism. Single nucleotide polymorphisms (SNPB) are also useful in forensics, paternity testing, genetic analysis and phenotype correlations to diseases. The present sequence is an example of one of the human gene SNPS shown in the specification
                                                                                                                                                                                                                      ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           The present invention provides a method of diagnosing a vascular disease in an individual, involving determining the sequence at various polymorphic sites within the human thrombospondin 1 and thrombospondin 4 genes. The sequences at a number of polymorphic sites are also provided in the specification. In particular, the method can be used in the diagnosis of atheroselerosis, myocardial infartion, coronary heart disease, stroke, peripheral vascular diseases, venous thromboembolism and pulmonary embolism. Single nucleotide polymorphisms (SNPs) are also
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Human, variant thrombospondin 1, variant thrombospondin 4; SNP; polymorphism; vascular disease; coronary artery disease; forensics; myocardial infarction; atherosclerosis; stroke; venous thromboembolism;

The present invention relates to a method for treating a patient diagnosed as having a lower than normal high density lipoprotein-cholesterol (HDL-C) level, a higher than normal triglyceride level, or a cardiovascular disease, involving administering a compound that modulates LXR. or RXR-mediated transcriptional activity or ABC1 expression or activity. The LXR gene product may be used in an assay to identify compounds useful for the treatment of a disease or condition selected a lower than normal HDL cholesterol level, a higher than normal triglyceride level, and a cardiovascular disease

Sequences AAH17205 - AAH40944 represent PCR primers, single nucleotide primers, and the sequences of regions flanking sites of single nucleotide polymorphisms SNPs. The present invention includes Kits for determining the presence or absence of a SNP, using the oligomucleotides are useful for genotyping a genotyping primer. SNP flanking sequence, the SNP primer is used as a genotyping primer. SNP flanking sequence, the SNP primer is used as a genotyping primer. The oligomucleotides are useful for genotyping a mucleic acid sample by performing a single-nucleotide primer extension reaction. The cligomucleotides are useful for determining the presence, absence or identity of a SNP and for genotype of an individual or group of individuals, having a pathological phenotypic trait suspected of being caused by one or more SNPs. Phenotypic traits include disease e.g. caused by one or more SNPs. Phenotypic traits include disease e.g. caused by one or more SNPs. Phenotypic traits include disease e.g. caused by one or more SNPs. Phenotypic traits include disease.

CC caused by one or more SNPs. Phenotypic traits include disease e.g. craits also include symptoms of or suscoplania, polycystic kidney disease.

CC traits also include symptoms of or suscoplinity to multifactorial disease of which a component is or may be genetic such as autoimmune diseases, including, rheumatoid arthritis, multiple solerosis, microorganism. The method is also useful in forensic investigations and microorganism. The method is also useful in forensic investigations and containing DNA sequence represents a PCR primer specific for a human SNP containing DNA sequence
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               ö

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              The present invention relates to a purified and isolated non-naturally occurring DNA ligands to basic fibroblast growth factor (bFGF). The ligands are useful as part of gene therapy treatments and for diagnosing pathogenesis of vascular diseases including initiation and progression of atherosclerosis, acute coronary syndromes, vein graft disease and restencis following coronary angioplasty. The ligands have improved
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Human, hypocretin receptor 1; orexin receptor 1; HCRTR1; chromosome 1; 1p33; central nervous system modulator; probe; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Novel nucleic acid ligands to basic fibroblast growth factor that are useful as inhibitors of basic fibroblast growth factors and 2'-amino modified RNA ligands, exhibit increased in vivo stability.

Probes AAFS5160-76 were used to identify a human hypocretin (orexin) receptor 1 (HCRTR1) gene. The HCRTR1 gene is present on chromosome 1, location 1p13. It is likely that a mutation in the HCRTR1 gene is associated with narcolepsy. HCRTR1 is a central nervous system modulator. The HCRTR1 polypeptide and polynucleotide are useful for diagnosing or treating narcolepsy in an individual. The HCRTR1 polynucleotide is a source of probes and primers, and is also used to produce the protein recombinantly
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Human, single nucleotide polymorphic; SNP; forensic science; paternity testing; phenotypic trait; genetic mapping; animal breeding; plant breeding; ds.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Gaps
Novel isolated nucleic acid molecule encoding hypocretin (orexin) receptor 1 useful for treating and diagnosing narcolepsy.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       /*tag= a

The present invention relates to human oligonucleotides comprising a single nucleotide polymorphic site (SNP: AAH88797-AAH89219). The present sequence is one such oligonucleotide. The oligonucleotides can be used in forensics, paternity testing, correlation of polymorphisms with phenotypic traits, genetic mapping of phenotypic traits and marker assisted breeding of animals and crop plants
                                                                                    New polymorphic sites derived from the human genome are useful to determine sites correlating with phenotypic traits, particularly disease, and also in forensics and paternity testing.
                                                                                                                                                                                                                                                                                                                                               Sequence 21 BP; 4 A; 9 C; 5 G; 3 T; 0 U; 0 Other;

New selenoprotein for use in detecting certain viruses, e.g. human immunodeficiency virus (HIV) or Ebola, cancer and immune system disorders

Disclosure; Col 69-70; 140pp; English

The present invention relates to selenoproteins encoded in the genome of a virus, where the coding sequence of the selenoprotein is genetically engineered for expression in a nucleic acid construct. The invention also discloses a method for identifying selenoprotein coding sequences, for detecting certain viruses (e.g. HIV or Ebola), cancer and immune system disorders. The present sequence was used to illustrate the invention

The present sequence comprises a probe for human papillomavirus (HPV)

C genotyping that was used in an example of the use of hairpin probes in

C mucleic acid hybridiaation analysis. The probe sequence is present within

the 5' stem portion of an RNA-DNA probe (see ABA91521) that is capable of

C forming a hairpin structure. The DNA protion of the hairpin probe

C includes methylphosphonates. The hairpin probe is immobilised onto a

membrane by BSA conjugation and the resulting probe-containing strip is

C contacted with HPV genomic DNA. After hybridised probe with RNA-DNA

structure. A second hybridisation is then performed using bictin-labelled

C probes, which are complementary to the portions of immobilised probe that

C become single-stranded after hybridisation and digestion. Biotin in the

C chemiluminescence. This is an example of the use of hairpin probes that

c are capable of both intrandolecular and internolecular hybridisation and

c n which the nucleotide sequence that is complementary to the target

C hairpin probe. The use of such probes reduces background hybridisation, ö Gaps .; 0 0.8%; Score 13.8; DB 1; Length 21; 88.2%; Pred. The invention relates to a nucleic acid comprising single nucleotide polymorphisms (SNPs) associated with diseases. The nucleic acids comprising the SNPs and probes and primers for detecting them may be used in assays for the diagnosis of diseases associated with SNPs (such as sickle cell anaemia, agammaglobulinaemia, diabetes insipidus, Lesch-Nyhan syndrome, mucular dystroppy, Wiskott-Addrich syndrome, Fabry's disease, familial hypercholesterolaemia, polycystic kidney disease, hereditary spherocytosis, Von Willebrand's disease, tuberous sclerosis, hereditary spherocytosis, Von Willebrand's disease, tuberous sclerosis, hereditary spherocytosis, Von Willebrand's disease, tuberous sclerosis, hereditary syndroms of or susceptibility to, multifactorial diseases of which a syndroms of, or susceptibility to, multifactorial diseases of which a component is or may be genetic, such as autoimmune diseases of which a inflammation, cancer, diseases of the nervous system, and infection by pathogenic microorganisms, autoimmune diseases including rheumatoid arthritis, multiple sclerosis, diabetes (insulin-dependent and non-carthritis, multiple sclerosis, diabetes (insulin-dependent), strength, speed, endurance, fertility, ovary, pancreas, prostate, skin, scomach and uterus, longevity, appearance (e.g., baldness, cobesity), strength, speed, endurance, fertility, and susceptibility or receptivity to particular drugs or therapeurometer treatments), in forensics and in paternity testing. Nucleic acid comprising single nucleotide polymorphisms, useful in forensics, paternity testing and diagnosis of disease. Claim 1; Page 46; 96pp; English.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               The invention relates to an isolated nucleic acid from a human gene encoding aminopeptidase P (XPNEP2), bradykinin receptor B1 (BDXBB1), tachykinin receptor B1 (TACR1), C1 esterase inhibitor (C1NH), kallikrein (KAK1), bradykinin receptor B2 (BDXRB2), angiotensin converting enzyme 2 (ACE2) or protease inhibitor 4 (P14), comprising at least one polymorphic position. Also included are (1) a probe that hybridises to a polymorphic position as provided in the detailed summary of single nucleotide polymorphisms comprising additional 5' and 3' flanking genomic sequence; (2) analysing (M1) at least one nucleic acid sample comprising obtaining the sample from one or more individuals and determining the mucleic acid sequence at one or more polymorphic positions in a gene encoding a protein selected from the group above; (3) constructing (M2)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             useful

haplotypes using the genes comprising grouping at least two nucleic acids (4) identifying (M3) an individual at risk of developing a disorder upon administration of an ACE inhibitor and/or vasopeptidase inhibitor using the polymorphic data; (5) a library of nucleic acids, each of which comprises one or more polymorphic positions within a gene encoding a human protein selected from the group above; and (6) genotyping (M4) an individual comprising obtaining a mucleic acid sample, determining the nucleotide present in at least one polymorphic position, and comparing at least one position with a known data set. The genes, (M1, M2, M3 and M4) and compositions are useful for detecting, disgnosing, treating, preventing various disorders such as angloedaema and diseases which involve anglogenesis like haemangiomas, tumours, sarcomas, Crohn's involve anglogenesis like haemangiomas, tumours, sarcomas, Crohn's involve anglogenesis like haemangiomas, tumours, sarcomas, Crohn's hypertension, heart failure, myocardial infarction, ventricular hypertension, heart failure, myocardial infarction, ventricular hypertension, heart failure, myocardial infarction, ventricular hypersensitivity reactions, sepsis, autoimmune diseases, inflammatory artery disease, and and/or atherosclerosis and/or artery disease, and disorders are listed in the specification). The obstructive pulmonary disease (COPD) and enterocollitis (many other diseases and disorders are listed in the specification) and bloodies are also useful for chromosome identification. Antibodies and biological samples. The present sequence is included in the sequence and biological samples. The present sequence is included in the sequence in the specification.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Aminopeptidase P; XPNEP2; bradykinin receptor B1; ds; BDKRB1; tachykinin receptor B1; TACR1; C1 esterase inhibitor; C1NH; kallikrein 1; KLR1; bradykinin receptor B2; BDKRB1; gene therapy; and addykinin receptor B2; BDKRB1; gene therapy; and converting enzyme 2; ACR2; protease inhibitor 4; P14; polymorphism; haemangioma; tumour; sarcoma; Crohn's disease; trachoma; cardiovascular disease; angina pectoris; hypertension; heart failure; myocardial infarction; ventricular hypertrophy; vascular disease; aneurysm; embolism; thrombosis; coronary artery disease; angloedaema; arteriosclerosis; atherosclerosis; hypersensitivity; sepsis; autoimmune disease; inflammatory arthritis; cancer; wound; viral infection; bacterial infection; fungal infection; COPD; chronic obstructive pulmonary disease; enterocolitis.

New isolated nucleic acid with at least one polymorphic position, useful for detecting, diagnosing and treating disorders such as angioedema, cancer, viral, bacterial or fungal infection, cardiovascular and

Disclosure; Page 809; 977pp; English.

The invention relates to an isolated nucleic acid from a human gene encoding aminopeptidase P (XPNEP2), bradykinin receptor B1 (BDXRB1), cleatezase inhibitor (CMR1), kallikrain teceptor B1 (TACR1), cleatezase inhibitor (CMR1), bradykinin receptor B2 (BDXRB2), angiotensin converting enzyme (CMLKA1), bradykinin receptor B2 (BDXRB2), angiotensin converting enzyme 2 (ACE2) or protease inhibitor 4 (P14), comprising at least one paymorphic position. Also included are (1) a probe that hybridises to a polymorphic position as provided in the detailed summary of single curl coloring polymorphisms comprising additionals and 3' flanking genomic sequence; (2) analysing (M1) at least one nucleic acid sequence at one or more polymorphic positions in a gene cuccing a protein selected from the group above; (3) constructing (M2) and polymorphic positions within a specencial adjocation and individual at risk of developing a disorder using the polymorphic data; (5) albrary of nucleic acids, each of which comparises one or more polymorphic positions within a spece encoding a comprises one or more polymorphic positions within a specencial of the polymorphic positions within a specencial of protein selected from the group above; and (6) genotyping (M4) and individual comparising at least one polymorphic position, and comparing at least one polymorphic position, and comparing the present in at least one polymorphic position, and comparing the present in at least one polymorphic position, thrombosis, coronary and compositions are useful for detecting, diagnosing, treating, and sease, trachomas, and cardiovascular diseases like angine pectoris, hypertrophy, vascular diseases, aneurysm, embolism, thrombosis, coronary artery disease, arterioral arterioral and engale and diseases which are polymorphic position, heart failure, myocardial infarction, ventricular hypersensitivity reactions, sepals, autoimmune diseases, inflammary disease, are listed in the specification). The polymucleotides are also useful for chromosome identification).

The invention relates to a novel human antibody (I), preferably a human monoclonal antibody which binds to an activation inducible lymphocyte immunoadulatory molecule (ALILM). (I) is useful for modulating signal transduction into a cell mediated by ALILM, for modulating proliferation of AILM-expressing cells, for modulating production of a cytokine from AILM-expressing cells, and for inducing antibody-dependent cytotoxicity against AILIM-expressing cells and/or immune cytolysis or apoptosis of AILM-expressing cells and/or immune cytolysis or apoptosis of AILM-expressing cells and/or immune cytolysis or apoptosis of Prophylaxis of delayed type allergy. (I) is useful for treating, preventing or preventing various diseases associated with AILIM-mediated costimulatory transduction, and for inhibiting the onset and/or advancement of the diseases. (I) is useful for suppression, prevention and/or treatment of

New human monoclonal antibody that binds to activation inducible lymphocyte immunomodulatory molecule, useful for treating rheumatoid arthritis, multiple sclerosis and inflammation.

Example 10; Page 247; 300pp; English.

The invention relates to an immunogenic composition of mycobacterial mutants with modified protein production capabilities. The invention also relates to methods for the treatment and prevention of infections also diseases. The methods and compositions of the invention are useful for vaccinating and treating infections in particular mycobacterial diseases such as tuberculosis and Crohn's disease. The invention is also used in gene therapy. The present sequence is a PCR primer used for amplifying Mycobacterium sp. hsp70 (heat shock protein 70) operon promoter. This

The present invention relates to a method of diagnosing a cellular proliferative disorder of breast tissue, which involves determining the state of methylation of one or more nucleic acids isolated from the state of methylation of the nucleic acids acompared with a state of methylation from a subject not having the cellular proliferative disorder of breast tissue is indicative of a cellular proliferative disorder of breast tissue is indicative of a cellular may be TWIST, HOXAS, NES-1, retinoic acid receptor beta (RARbeta), oestrogen receptor, cyclin D2, Wilms' tumour gene (WT-1), 14.3.3 sigma, HN-10 r RASSFR. The method is useful for diagnoshig and/or determining a predisposition to a cellular proliferative disorder, in particular breast cancer including ductal carcinoma in situ, lobular carcinoma, colloid carcinoma, tubular carcinoma, medullary carcinoma, metaplastic carcinoma, intraductal carcinoma, medullary carcinoma in situ and papillary carcinoma in situ. The present sequence is a primer used in the exemplification of the invention
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                proliferative disorder of breast tissue, in particular breast cancer, by determining the state of methylation of one or more nucleic acids isolated from the subject.

Isolated nucleic acid molecules having polymorphisms in known human genes eg. cytochrome p450 and cathepsin S useful as genetic linkage markers for locating, identifying and characterizing the genes responsible for disorder-related traits.

Example 9; Page 115; 714pp; English.

This invention relates to the sequence of an isolated nucleic acid molecule comprising at least one base variation from that of a known molecule comprising at least one base variation from that of a known wolconome P450 A1 (CY45510A1), atcremented A2 (CY4551A2), cytochrome P450 D2E1 (CY4550D2E1), adrenergic receptor beta1 (ADDR1), aryl hydrocarbon receptor nuclear translocator (ARNT), cathepsin 8 (CYS2), cytloxygenase 2 (GXOZ), diazepam binding inhibitor (DBI), epoxide hydroxylase 2 (EMXZ), 5-lipoxygenase activating protein (FLAP), glutathione-S-transferase 12 (GXI12), histamine-N-methyl transferase (HNWT), NADPH quinone oxidoreductase 2 (NQOZ), sulfotransferase (HNWT), NADPH quinone oxidoreductase 2 (NQOZ), sulfotransferase thermolabile (STM), UDP-glucuronosyl transferase 2B7 (UGT2B7), UDP-glucuronosyl transferase (UGT2B1), urokinase receptor (URPS), multidrug resistance 1 (MDR1), actotransferzin (LTF), unltidrug resistance associated protein 3 (MRP3), orphan nuclear receptor (NRIIZ), or acetylcholine muscarinic

The polymorphisms in the human genes cited in the invention are useful as genetic linkage markers for locating and characterising the genes that are responsible for specific traits within the genome and eventually identifying the genes responsible for a variety of disorder-related trains as a result of thair e.g., overexpression, constitutive expression, mutation or underexpression, which may be used in diamosing and/or treating the disorders. The nucleic acid molecules comprising the polymorphic sequences contained in CYP4501A1, CYP4510A2, ARNY, BEHX, GST12, NNMY, NQC2, NR112, STW, UGT2B4, UGT2B5, AHR, MDR1 and/or MDR3 are useful for screening individuals for altered drug metabolism. The polymorphic sequences contained in CYP4501A1, CYP4501A2, ARNY, MDR1 and/or MDR3 may also be used to screen individuals for altered central used to screen for altered cardiovascular function, in COX2 for altered central nervous system function, in FADP and HNWY for altered pulmonary, immological the metabological function, in FADP and HNWY for altered serine function, in FADP and HNWY for altered immunological or haematological function, in FADP and HNWY for altered central and peripheral nervous system function, in CHNR3, CHNR4 for Altered central and peripheral nervous system function. The present sequence represents a polymorphic DNA sequence of the invention

New recombinant dimethyl sulfide:acceptor oxidoreductase or its subunits, useful for oxidizing prochiral organic sulfides to form sulfoxide enantiomers for chiral drug synthesis.

Claim 15; Page 46; 66pp; English.

The invention relates to a recombinant dimethyl sulphide (DMS):acceptor oxidoreductase (I) or its subunit selected from recombinant alpha, beta, delta and gamma subunits. (I) is useful for oxidising prochiral organic

```
The invention describes a polymuclectide (I) of the endothelin (EDN)/endothelin converting enzyme (ECE)/receptors of EDN and ECE (EDNR) signaling system which is associated with a cardiovascular disease. (I), the gene encoding EDN, ECE or EDNR (II) or a vector (III) expressing (I) or (III) is useful for producing cells capable of expressing a molecular variant polypeptide which is associated with a cardiovascular disease. (II), (III), the EDN, ECE or EDNR FOLYPEPTIGE, or a cardiovascular disease. (II), till), the EDN, ECE or EDNP polypeptide, or a cardiovascular disease obtaining a pro-drug or drug capable of modulating the activity of a molecular variant of a polypeptide of the EDN/EDNR/ECE signaling system or its gene product, or for identifying and obtaining an inhibitor of the activity of a molecular variant of a polypeptide of the EDN/EDNR/ECE
                                                                                                                                                                                                                                                                                  ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Novel polynucleotide of the endothelin/endothelin converting enzyme signaling enzyme system associated with cardiovascular disease, useful for treating the
               is expressed in a transformed bacterium. The enantiomer formed is useful actor producing a chiral drug. (I) is useful for spribesis of optically-active functional groups of drug. DNA encoding (I) is useful for producing a strain of DMS:acceptor oxidoreductase- deficient Rhodovulum sulfidophilum, which is useful in whole-cell reaction, where DMS:acceptor oxidoreductase activity is unwanted. ABK53751-ABK53805 represent R. sulfidophilum DMS:acceptor oxidoreductase subunit coding sequences and
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Endothelin; EDN; endothelin converting enzyme; ECE; endothelin receptor; EDNR; signaling system; cardiovascular disease; coronary heart disease; hypertension; atherosclerosis; angliogenesis; farty acid metabolism; diabetes; familial hypercholesterolaemia; forensic marker; transgenic animal; solid support; cardiovascular regulator; SNP; single nucleotide polymorphism; PCR; primer; ss.
to form sulphoxide enantiomers for chiral drug synthesis. (I)
                                                                                                                                                                                                                                                                                    Gaps

signaling system or its gene product. The isolated proteins and polynucleotides encoding them are useful for preparation of a pharmacutical composition for treating a cardiovascular disease such as coronary heart disease, hypertension, atherosclerosis, or related to abnormal angiogenesis or fatty acid metabolism e.g. diabetes and familial hypercholesterolaemia. The gene or a polynucleotide fragment of the EDN/ECE/EDNR signaling system are useful as forensic markers, for creating a transgenic animal and in creation of a solid support comprising polynucleotides, genes, vectors, polypeptides, antibodies or host cells of the invention. This sequence represents a PCR primer used to identify single nucleotide polymorphisms in DNA encoding cardiovascular regulator proteins of the EDN/ECE/EDNR signaling pathway
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      The invention describes a polymucleotide (I) of the endothelin (EDNR)/endothelin converting enzyme (ECE)/receptors of EDN and BCE (EDNR) signaling system which is associated with a cardiovacular disease. (I), the gene encoding EDN, ECE or EDNR (II) or a vector (III) expressing (I) or (II) is useful for producing cells capable of expressing a molecular variant polypeptide which is associated with a cardiovaccular disease. (II), the EDN, ECE or EDNR polypeptide, or a cell expressing a molecular variant game comprising (I) is useful for identifying and obtaining a pro-drug or drug capable of modulating the activity of a
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Endothelin; EDN; endothelin converting enzyme; ECE; endothelin receptor; EDNR; signaling system; cardiovascular disease; coronary heart disease; hypertension; atherosclerosis; angiogenesis; tatty acid metabolism; diabetes; familial hypercholesterolaemia; forensic marker; transgenic animal; solid support; cardiovascular regulator; SNP; single nucleotide polymorphism; PCR; primer; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Endothelin converting enzyme 1 (ECE-1) SNP detection primer #143.

molecular variant of a polypeptide of the EDN/EDNR/ECE signaling system or its gene product, or for identifying and obtaining an inhibitor of the activity of a molecular variant of a polypeptide of the EDN/EDNR/ECE signaling system or its gene product. The isolated proteins and polymucleotides encoding them are useful for preparation of a polymucleotides encoding them are useful for preparation of a pharmaceutical composition for treating a cardiovascular disease such as coronary heart disease, hypertension, atherosclerosis, or related to abnormal angiogenesis or fatty acid metabolism e.g. diabetes and familial hypercholesterolaemia. The gene or a polymucleotide fragment of the CEN/EE/EDNR signaling system are useful as forensic markers, for creating a transgenic animal and in creation of a solid support comprising polymucleotides, genes, vectors, polypeptides, antibodies or host cells of the invention. This sequence represents a PCR primer used to identify single nucleotide polymorphisms in DNA encoding cardiovascular regulator proteins of the EDN/ECE/EDNR signaling pathway
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Determining an individual's risk for type 1 diabetes, comprises detecting the presence of an insulin dependent diabetes mellitus-associated interleukin 4 receptor allele in a nucleic acid sample of the individual.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Human; interleukin 4 receptor; IL4R; type 1; diabetes; allele; insulian dependent diabetes mellitus; IDDM; myasthenia gravis; single nucleotide polymorphism; SNP; autoimmune disease; T helper type 1 mediated disease; rheumatoid arthritis; probe; multiple solerosis; inflammatory bowel disease; systemic solerosis; systemic lupus erythematosus; psoriasis; soleroderma; Grave's disease; Guillain-Barre syndrome; Hashimoto's thyroiditis; so.

```
mellitus (IDDM)-associated interleukin 4 receptor allele in a nucleic acid sample of the individual, where the presence of the allele indicates the individual's risk for type I diabetes. The method identifies one or more single nucleotide polymorphism (SNP) within the ILMR gene listed in the specification. The method and the SNP's are useful for determining an individual's risk for type I diabetes. The ILMR SNPs are also useful for determining an individuals risk for any autoimmune disease or condition or any T helper type I mediated disease, e.g. rheumatoid arthritis, multiple sclerosis, inflammatory bowel disease, systemic lupus sclerosis, mysathenia gravis, Guillain-Barre syndrome, or Hashimoto's thyroiditis
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Determining an individual's risk for type 1 diabetes, comprises detecting the presence of an insulin dependent diabetes mellitus-associated interleukin 4 receptor allele in a nucleic acid sample of the individual.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  The sequences given in ABQ80153-69 represent probes which were used to identify wild type and variant loci in the human interleukin 4 receptor (ILAR). These probe sequences were used in the method of the invention for determining an individual's risk for type 1 diabetes. The method comprises detecting the presence of an insulin dependent diabetes andlitus (IDDM) associated interleukin 4 receptor allele in a mucleic acid sample of the individual, where the presence of the allele indicates the individual's risk for type 1 diabetes. The method identifies one or
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Human; interleukin 4 receptor; ILAR; type 1; diabetes; allele; insulin dependent diabetes mellitus; IDDM, wyasthenia gravis; single nucleotide polymorphism; SNP; autoimmune disease; T helper type 1 mediated disease; rheumatoid arthritis; probe; multiple sclerosis; inflammatory bowel disease; systemic sclerosis; systemic lupus erythematosus; psoriasis; scleroderma; Grave's disease; guillain-barre syndrome; Hashimoto's thyroiditis; ss.

These probe sequences were used in the method of the invention for determining an individual's risk for type 1 diabetes. The method comprises detecting the presence of an insulin dependent diabetes

more single nucleotide polymorphism (SNP) within the IL4R gene listed in the specification. The method and the SNP's are useful for determining an individual's risk for type 1 diabetes. The IL4R SNP's are also useful for determining an individual's risk for any autoimmune disease or condition or any Thelper type 1 mediated disease, e.g. rheumatoid arthritis, multiple sclerosis, inflammatory bowel disease, systemic lupus schematosus, psoriasis, scleroderma, Grave's disease, systemic thynsolatis, myasthenia gravis, Guillain-Barre syndrome, or Hashimoto's thyroiditis

Dattagupta N, Tseng T;

Detecting point mutation in DNA strand, by hybridizing target DNA strand having mutation with test DNA strand to form duplex, contacting the duplex with RNase H and determining the cleavage of test strand by RNase

Example 1; Page 12; 26pp; English.

The invention relates to a novel method for detecting a point mutation in a DNA strand. The novel method comprises hybridishing a target DNA strand containing or suspected of containing a point mutation with a test nucleic acid strand complementary to the DNA strand to form a target DNA strand/test nucleic acid strand duplex, contacting the duplex with an strand/test nucleic acid strand duplex, contacting the duplex with an enclosive H, and determining whether the ribonucleotide residues within the nucleotide sequence are cleaved by RNase H. The method is useful for detecting a point mutation in a DNA strand, where the point mutation to be detected is a single nucleotide polymorphism, preferably a colymorphism in a genome, e.g., a viral, bacterial, eukaryotic, mammalian or human genome. The method is useful to detect any nucleic acids from any species of organisms such as Acintobacter, Bacillus, Candida, Enterococcus, Heemophilus, Mycobacterium and Streptococcus, and viruses. This polymucleotide sequence represents a probe relating to the mutation detecting method of the invention

This invention relates to a novel method of identifying candidate p53
pathway modulating agent which comprises contacting an assay system
comparising stearyl coenzyme A desaturase (SCD) polypeptide or nucleic
agent under conditions where, but for the presence of the test agent, the
system provides a reference activity. The p53 gene is mutated in over 50
different types of human cancer and is believed to be the most commonly
mutated gene in human cancer. The human p53 protein normally functions as
a central integrator of signals including DNA damage, hypoxia, nucleotide
optivation and oncogene activation. Modulators of p53 may have
carrial integrator of signals including DNA damage, hypoxia, nucleotide
optivation and oncogene activation. Modulators of p53 may have
invention are useful for identifying modulators of p53 may have
therapeutic targets for disorders associated with defective p53 function,
such as anglogenic, apoptotic or cell proliferative disorders, for
cample cancer. The modulators are useful as research reagents,
clasmostics and therapeutics. The present sequence (see ) small
chat of a human Stearoyl-CoA desaturase 4 sequence (see ) small
interfering RNA (siRNA) used in the exemplification of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             0

The present invention provides the gene, protein and cDNA sequences of the human melanocortin 2 receptor (adrenocorticotrophic hormone) (WC2R). Also identified are a number of single nucleotide polymorphisms (SNPS) found within the sequences. The sequences can be used to find the haplotype of the MC2R gene in an individual and to identify drugs for the reatment of cancer and familial glucocorticoid deficiency. The present sequence is an allele specific primer for the gene of the invention, which is found on chromosome 18q11.2
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 constituent of gag gene of HIV-1 Bru, -Mal or -Eli, HIV-
                                                                                                                                                                                                                                                  Melanocortin 2 receptor (MC2R) gene polymorphic variants, useful e.g. in studying the expression and function of MC2R and screening candidate drugs for treating familial glucocorticoid deficiency and cancer.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           셤
```

```
The sequence is that of a detection step primer for use in the identification of a mutation (G -> A) in the second mucleotide of codon 12 of the N-ras gene. It corresponds to nucleotides 15 to 34 on the N-ras gene and was synthesised on an Applied Biosystems 381A DNA synthesiser. It allows the accurate determn. of changes in the N-ras gene with such efficiency and ease that large numbers of samples can be screened. See also AAQ13677-Q13689. (Updated on 25-MAR-2003 to correct PA field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Detection of specific nucleotide variations - by primer extension using a detection step primer immediately adjacent the variable nucleotide.
                                                                                                                                         This nuclectide sequence is found in posn. 1388-1369 of HIV-1 Bru, 1421-1403 of HIV-1 Mal, 1388-1369 of HIV-Eli, 1706-1687 of HIV-2 ROD and 1670-1651 of SIV-MAC. It is the anti-sense strand of a primer pair used to amplify these HIV-1, HIV-2 and SIV viral sequences, esp. in conjunction with in vitro diagnosis of in-fection. It is useful for treating viral diseases, eg. AIDS. See also AAQ06905-08 and AAQ06910-54. (Updated on 09-JAN-2003 to add missing OS field.)
                                        New nucleotide sequences derived from genome of HIV-1, HIV-2 and SIV useful as primers for amplification of immuno-deficiency viruses in diagnosis and for raising antibodies in treatment of HIV infections.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   N-ras gene codon 12 nucleotide variation detection step primer.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            This antisense oligonucleotide was designed to hybridise to the 3'-UTR thuman ICAM-1 mRNA. It was synthesised in the phosphorothicate form as none of the phosphodiester form-antisense oligonucleotides which were initially tested demonstrated inhibitory activity. Oligonucleotide #15 was found to be the most active of 16 potentially inhibitory anti-sense sequences. Its anti-sense activity was not shared by other oligonucleotides which hybridise to 3'-untranslated sequences. See e.g.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   New oligonucleotides hybridisable to cell adhesion modulators - for treatment and diagnosis of e.g. allograft rejection, cancer, AIDS etcand diagnosis of intercellular adhesion dysfunction.

                                                                                                                                                                                                                               The sequences given in AAQG6488-90 are primers which were used in the method of the invention for the detection of a mutant oncogene. The method allows the detection and measuring a mutant oncogene contained in a sputum sample. PCR is performed by utilising the mutation position of the objective mutant oncogene as the complementary base to the 3' there by a bring a mixture of three primers which are different from teh the normal sequence at the 3' terminus. Another primer is used to hold the mutant oncogene together so that the mutant oncogene can be amplified position specifically and detected is pref. the K-ras gene and the mutation to be detected is pref. either codon 12, 13 or 61. This method allows detection of a mutation which is present only in trace amounts in the test sample
                                                                                                                                                                                                                                                                                                                                                                                                                      ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Human intercellular adhesion molecule; ICAM-1; cell adhesion; modulation; inflammation; psoriasis; malignant melanoma; inflammatory bowel disease; antisense oligonucleotide; therapy; ss.

A deleted version of the core gene, referred to as core delta
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Antisense oligonucleotides which target human ICAM-1 were synthesised in both the phosphodiester and phosphorothioate forms. The oligonucleotides are useful to treat diseases which are modulated by changes in intercellular adhesion molecules. This sequence corresponds to nucleotides 1952-1971 of the 3'- untranslated region of the human ICAM-1 coding sequence. (Updated on 25-MAR-2003 to correct PN field.)
                                                                                                                                                                                                                                                                                                                                            Oligo:nucleotide modulation of cell adhesion - used in the treatment of e.g. psoriasis, inflammatory bowel disease or malignant melanoma.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Prevention and treatment of hepatitis - using recombinant replicable vaccinia viruses contg. hepatitis B virus surface and core antigen
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    Sequence of PCR primer for modified HBV core antigen core delta 8.

8, in which 8 AAs are deleted, was used. A construct was made consisting of HBV MS antigen expressed from the modified p7.5 promoter and core delta 8 expressed from the p7.5 promoter. One primer used was AAQ67992 which hybridises from bases -230 to -211 relative to the ATG of core delta 8, upstream of the p7.5 promoter, and creases a HindIII site. A second primer (AAQ67993) hybridises to the opposite strand from bases +553 to +546 and generates a HindIII site. (Updated on 25-MAR-2003 to correct PN field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  AAQ71022 and AAQ71023 are primers for the DNA sequence (AAQ79199) that codes for the rat mu-subtype opioid receptor (AAR65188). Rapid detection of Brucella may be achieved by amplifying the omp2 gene locus of Errcella (which shows genetic variation correlating with established species designations) and hybridising the amplified sequence with a panel of DNA probes to identify a species of biovar of Brucella. The amplified sequence is preferably a sequence between nuclectides 2470 used for the consensus sequence described in AAQ1479. The method is used for the detection of Brucella infection in animals, particularly humans and cattle. This probe specifically hybridises to sequences from Brucella abortus biovar 1, Brucella abortus biovar 5, Brucella melitensis, Brucella neotomae and Brucella ovis which are amplified by the primers described in AAQ71496 and AAQ71497. The use of an array of probes (See AAQ71495-509) allows specific identification of the species of Brucella. (Updated on 25-MAR-2003 to correct PF field.)

subunits are consists of the nucleobases attached covalently
to a polyamide backbone"
                                                                                                                                                                PCR primers (AAQ91246-50) were used to amplify human glutamate receptor EAAS genomic DNA and cDNA. Examination of the PCR products showed that the cDNA sequence differed from the genomic Sequence at 2 places in the transmembrane domain-coding region, resulting in S310A and R5220 substitutions. These variations were attributed to RNA editing involving T to G and G and A substitutions. Similar RNA editing was found for EAA3 (see also AAQ91231) and EAA4 (see also AAQ91232) genes

New oligomers are claimed which (A) have at least one peptide nucleic acid (PNA) subunit and (B) have a sequence hybridisable to AUG region.

Coding region, 5'-untranslated region or 3'-untranslated region of ICAM-1 or ELAM-1, or hybridisable to AUG region, coding region, 5'- untranslated region of UCAM-1 or ELAM-1, or hybridisable to AUG region, coding region, exon/intron junction region or 3'-untranslated region of VCAM-1.

The PNAs can be used to target RNA and single stranded DNA (SDNA) to produce antisense-type gene regulation moieties. Hence they may be used therepoetically for modulating cellular adhesion and thus as an antimetastatic agents, anticancer agents, anticancer agents, anticancer agents, antiching callular adhesion and thus as an antimetastatic agents, anticancer agents. They may also be useful as antimetastatic agents, anticancer specific mRNAs. PNA oligomers have high affinity for complementary single stranded DNA. They are also able to form triple helices in which a first PNA strand binds with the resulting double helix or with the first PNA strand. The PNAs possess no significant charge and are water soluble, which facilitates cellular uptake. Further, since they contain amides of non-biological amino acids, they are bloestable and resistant consymatic degradation by proteases. The present sequence targets human cut intercellular adhesion molecule-1 (ICAM-1) 3' untranslated region
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               ô
New peptide nucleic acid oligomers hybridising to adhesion molecule genes - are stable anti:sense cpds. of high affinity, partic. for treating inflammation, viral infection, cancer etc.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Wild-type multiple tumour suppressor (MTS) gene and mutant sequences - useful in diagnosis, prognosis and therapy of human cancer, e.g. melanoma

                                                     The cDNA sequences encoding several multiple tumour suppressor (WTS) polypeptides have been isolated and sequenced, using various sequencing and amplification primers. AAG99936-40 are oligomuclectides used to amplify CDNA encoding mouse WTSIE1-beta to allow comparison of the human and murine sequences. WTS polypeptide-encoding cDNAs and mutants of themen are useful for the diagnosis or prognosis of human cancer. Germ-line mutations of MTS cDNAs can be used for diagnosing predisposition to melanoma, leukaemia, astrocytoma, glioblastoma, lymphoma, glioma, Hodgkin's lymphoma, CLL and cancers of the pancreas, thyroid, ovary, Hodgkin's lymphoma, testis, kidney, stomach and rectum. The wild-type gene is useful for gene therapy and MTS polypeptides may also be used for protein replacement therapy. Also the polypeptides or cells contg. an altered MTS gene are useful for screening for potential cancer therapeutics
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           AAQB1115 is a peptide nucleic acid (PNA), which binds a target sequence. The binding of the PNA prevents the transcription of the target sequence
                                                                                                                                                                                                                                                                                                                                                Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Peptide nucleic acid; gene therapy; transcription arrest; diagnosis;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Use of oligonucleotide analogues, partic. peptide nucleic acids

The binding of the PNA prevents the transcription of the target sequence by RNA polymerase. The ability of the PNA to arrest transcription makes it useful in gene therapy, and in diagnostic and prophylatic methods. (Updated on 25-MAR-2003 to correct PN field.)
by RNA polymerase. The ability of the PNA to arrest transcription makes it useful in gene therapy, and in diagnostic and prophylatic methods. (Updated on 25-MAR-2003 to correct PN field.)

The above assay can also be used in the diagnosis and prognosis of melanoma, lymphoma, leukaemia and pancreas, breast and thyroid cancers, etc

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     A probe of approximately 1 kb recognising beta-giardin genomic DNA was generated by PCR with the oligonucleotides AAQ80942 and AAQ80943. A random probe was generated as a 1.5 kb product with the primers AAQ80944 and AAQ80945. The probes were used in the identification of cosmids from the beta-giardin genomic region in a diardia lamblia 20-genome equivalent cosmid library. This was part of a novel method for sequence-sampled mapping of complex genomes. (Updated on 25-MAR-2003 to correct PN field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     ል
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Sequencing complex genomes, present as fragments in a cosmid library - k sequencing end-specific nucleotides of each clone then correlating with spatial relationship of cosmid, esp. for mammalian chromosomes.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Multiple tumour suppressor; MTS1; cancer; diagnosis; assay; predisposition; melanoma; leukaemia; lymphoma; prognosis; pancreas; breast; thyroid; P16 specific; reverse PCR primer; ss.

The antisense oligonucleotide (ON) shown is a derivative of an equivalent wild type Human ICAM ON, in which at least one, esp. 2-10, non-terminal pyrimidine nucleotide(8) is/are modified. The modification may be: (a) replacement of a phosphodiseter linkage by: a phosphoro-thioate (PS), dithioate, aramidate; borano-, alkyl-, aralkyl-phosphore: 2,2.2-trichloro-1, Idimethyl-, alkyl- or aryl- phosphorate linkage; or (3'-thio) formacetal, methylhydroxylamine, oxime, methylenge; to replacement of a sugar dimethylene sulphone or silyl linkage; (b) replacement of a sugar phosphorae backbone by a "morphholinonucleoside" oligomer; (c) replacement of beta-D-2-deoxyribose by another sugar or carbocyclic, open-chain or bicyclic sugar analogue, or (c) replacement of the natural nucleoside base by an analogue, e.g. 5-hydroxymethyl-uridine. The 5' and/or 3' terminus may also be modified with a lipophilic gp, eg, a farnesyl. The modifications increase nuclease resistance and thus improve stability and
                 New anti:sense oligo:nucleotide analogues - with modified non-terminal pyrimidine nucleotide units, useful for treating viral infections,
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Gene signature; messenger RNA; mRNA; relative abundance; frequency; human; cloning; mapping; non-biased library; diagnosis; detection; cell typing; abnormal cell function; primer; PCR; amplification; polymerase chain reaction; ss.

0; Gaps

Single-stranded DNA for identifying gene signatures - isolated from 3'-directed human cDNA library that reflects relative abundance of corresp. mRNA in specific human tissues.

Primers T41001-T41382 are derived from novel human gene signature (GS)

Example 7; Fig 10; 2245pp; Japanese.

```
ö
sequences which did not match with sequences deposited in Genbank release 76. The GS sequences (T19001-T26837) were obtained from 3'-directed cDNA libraries prepared from various human tissues, synthesis of cDNA was initiated from the 3'-end of mRNA by using poly(T) as the sole primer. Bach library is constructed so as to reflect accurately the relative abundance of different mRNAs in the particular tissue from which it was determined (sp. using primers and probes derived from the GS sequences) as a means of diagnosing abnormal cell function or for recognising different cell types. The primers $71335-6 amplify clone pm0268 which comprises the GS HUMSS000955 (T19995). This amplification reaction gave prod. indistinguisable from the same PCR using mouse or Chinese hamster
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 A sense oligonucleotide S50 (AAQ99516) corresp. to nucleotides 50-69 in the human Fas ligand coding sequence given in AAT03498 was synthesised with phosphororhioate linkages. The complementary, antisense oligonucleotide A69 (AAQ99517) was also synthesised. The effects on Fas ligand-mediated apoptosis of A69 and S50 were analysed
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Peptide which binds to Fas antigen, and antibody reactive with it - for treatment and diagnosis of viral or auto:immune diseases.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Fas ligand, Tumour Necrosis factor family; apoptosis; cell death; Fas cell surface antigen; human; Fas-L; phosphorothioate; antisense oligonucleotide; inhibition; ss.

New oligo:nucleotide(s) contg. 8-aza:purine base - useful as therapeutic and diagnostic agents with more stable hybridisation to target nucleic
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 AAT44425-54 are antisense oligonucleotides which have at least one 8-azapurine base. The presence of an 8-azapurine base results in significantly stronger complexing when hybridising to target nucleic acids. The present sequence is against the intracellular adhesion molecule (ICAM) gene
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Antisense therapy; guanosine; intercellular adhesion molecule; ICAM; nuclease resistance; stability; ss.

This sequence represents an inhibitor of ICAM, and is an example of an oligonucleotide analogue of the invention. The oligonuclectide analogues of the invention are used as inhibitors of gene expression (antisense oligonuclectides, ribozymes, sense oligonuclectides and triplex-forming oligonuclectides), as probes for the detection of nucleic acids, and as auxiliaries in molecular biology. As gene expression inhibitors they may be used for treating viral infections (especially where the virus is HSV-
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Gene expression inhibitor; probe; nucleic acid detection; growth factor; viral infection; therapy; HSV-1; cancer; restenosis; integrin; cell-cell adhesion receptor; ICAM; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                New phosphono:mono:ester oligo:nucleotide analogues - inhibitors of gene expression for treating viral infections, cancer, restenosis, etc.
                                                Oligo:nucleotide(s) with series of G residués at at least one end have increased stability against nuclease and cell penetration, - are partic. anti:sense sequences for treating and diagnosing cancer, viral diseases
                                                                                                                                                                           Ten- to 40-mer oligonucleotides which have a cap of 1-10 (esp. 4) G residues on at least one end are provided; if caps are present at both ends, they can be of the same or different lengths. A cap sequence increases nuclease resistance of the oligonucleotide and also increases cell penetration. The present sequence is that of a preferred oligonucleotide, directed against an intercellular adhesion molecule sequence, which can be capped for use in anticancer therapy
                                                                                                                                                                                                                                                                                                                                                             o.8%; Score 13.6; DB 1; Length 20; Similarity 80.0%; Pred. No. 9.3e+02;

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    The F1 Min/Immortomouse and conditionally immortalised cell lines derived from this mouse, carrying the Multiple Intestinal Neoplasia (Min) gene, which predisposes to colon cancer, and a temperature sensitive mutant of the SV40 large T gene which allows growth at certain temperatures, are useful in studies of aberrations of growth and differentiation, including carcinogenesis that may be induced, e.g. by viruses, various genes or mutagens. PCR analysis was carried out to detect the presence of the SV40 large T gene and the Min mutant allele. Most preped. from tail tissue of mice greater than 2 weeks of age. AAT15586-87 which were used to test for the presence of the Min mutant allele, produced a 280 bp PCR
1, HSV-2, an influenza virus, VSV, hepatitis B or papilloma virus), cancer, restenosis, medical conditions mediated by integrins or cell-cell adhesion receptors, and medical conditions induced by growth factors
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Transgenic animals contg. an immortalising gene and intestinal neoplasia-
associated gene - useful in studies of e.g. carcino-genesis, that may be
induced by e.g. viruses, various gene or mutagens.

AAT30211-T30233, AAT33058-T33112 and AAT36667-T36684 represent antieense oligonuclectides of the invention. These sequences target regions of the coding sequences for human intercellular adhesion molecule-1 (ICAM-1), endothelial leukocyte adhesion molecule-1 (ELAM-1, also known as Eschectin), or vascular cell adhesion molecule-1 (VCAM-1). This sequence targets the 3' untranslated region (uncleotides 1952-1971) of ICAM-1. ICAM-1, ELAM-1, and VCAM-1 represent three of the five cell adhesion molecules involved in the adherence of white blood cells to vascular endothelium. These sequences can be used in a composition for treating callograft rejection. The composition contains one of these sequences in combination with an immunosuppressive agent. The immunosuppressive agent cused in the compositions is brequinar, rapamycin, anti-lymphocyte serum, a monoclonal antibody against LFA-1 or an antisense oligonucleotide. The such as cardiac or renal allograft rejection. By using these compositions, allograft rejection. By using these compositions, allograft rejection. By using these

```
This invention describes novel phosphonomonoester oligonuclectide analogues which act as inhibitors of gene expression (as sense/antisense, ribozyme or triplex-forming molecules), useful as diagnostic agains (i.e. probes for detecting nucleic acid) or for treatment of diseases caused by viruses, influenced by integrins or cell-cell adhesion receptors, induced by factors such as TMF-alpha, or cancer or restencies. The products of the invention satisfy the requirements of good in-vivo stability; ability to cross cellular and nuclear membranes, and specific binding to target nucleic acid better than known oligonucleotides
                                                                                                                        Phosphonomoncester analogue; inhibitor; antisense; cancer; restenosis; ribozyme; diagnostic agent; detection; treatment; disease; virus; integrin; cell-cell adhesion receptor; TNF-alpha; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Antisense; anti-proliferative; tumour; cancer; raf; oncogene; phosphorothicate; 2' sugar modification; psoriasis; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                            New oligo:nucleotide analogues contg. phospho:mono:ester bridges -
therapeutic inhibition of gene expression, e.g. in cancer or viral
infection, with good specificity and in vivo stability.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                ö

incorporate a ribozyme structure, or a pendant group"
                                          Human and mouse pancreatic ATP sensitive potassium channel proteins - fo:
diagnosis, therapy and research into potassium channel related diseases,
e.g. diabetes.
                                                                                                                                                             PCR primers (AAT61868-79) were designed to amplify subregions A-F of the human pancreatic ATP sensitive potassium channel beta-IR gene (see also AAT61866). The antisense primer (AAT61877) for subregion B (494 bp) corresponds to nucleotides 999-1019 of the gene. Cy5-labelled primers were used in the PCR-SSCP analysis of genomic DNA collected from 20 healthy Japanese subjects
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         The present sequence represents a novel oligonucleotide 3(3B) MRP that
                                                                                                                                                                                                                                                                                                                                                                                Gaps

                                                                                                                                                                                                                                                                                                                                                                                                                                     AAT27481-T27507 are human c-raf kinase antisense oligonucleotides used for the inhibition of raf expression. The oligonucleotides (ONs) are trageted to either codding region, start or stop signals or 5' or 3' untranslated region (UTR) mNAN encoding human c-raf. The ONs may be phosphorothioate linked and may contain modifications at the 2' position of the sugar molety. ONs are pref. complementary to either 3' or 5' UTRs, phosphorothioate linked and contain 2''O-alkyl sugar modifications. The ONs are used to inhibit expression of human raf in partic. in conditions associated with hyperproliferation e.g. cancer, restenosis, and psoriasis
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           ATP-sensitive potassium channel protein; beta-IR; diabetes; pancreas; beta-cell; diagnosis; gene therapy; primer; PCR; polymerase chain reaction; single strand conformation polymorphism; SSCP;

specifically hybridises in a human cell with a complementary sequence of human multidrug resistance-associated protein (RRP) gene. Hybridisation causes inhibition of expression of the multidrug resistance phenotype by the cell, due to the oligomucleotide having an aprameric inhibitory effect as well as an antisense inhibitory effect. The oligomucleotide is administered to cancer patients to prevent development of the multidrug resistant phenotype. When co- administered with chemotherapeutic agents, the oligomucleotide is useful for potentiating alimination of multidrug resistant tumour cells from home marrow or peripheral stem cell grafts. Also, the oligomucleotide can be used as an immunosuppressive agent
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    Primer; polymerase chain reaction; PCR; amplification; P16; promoter; ss.

comprising conserved sequences of human immunodeficiency virus and simian
immunodeficiency virus genes.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      The oligonucleotides AAT98010-T98059 are useful as primers for nucleic acid amplification of conserved sequences of the gag, vpr. pol or vpu genes of the HIV-1 strains Bru, Mal, Bil, HIV-2 ROD or sinian immunodeficiency virus (SIV) MAC or the nef2, vif2 or vpx genes of HIV-2 ROD and SIV MAC. This primer is targetted to sequences in the gag gene of the viral strains. The sequence are therefore used to detect HIV-1, HIV-2 or SIV infections. (Updated on 25-MAR-2003 to correct PR field.) transmembrane regulator (CFTR) gene. These sequences can be used as half transmembrane regulator (CFTR) gene. These sequences can be used as half of the chimeric primers of the invention. The primers are used for amplification of a target DNA sequence, and can be used in a multiplex per amplification. The primers have the sequence 5'-XY-3', where X is a sequence that does not hybridise to the target sequence (such as APT47344 and Y is a sequence contained within or flanking the target requence (such as this sequence). During early cycles of amplification, products are synthesised that contain the chimeric primers on either end. The primers then serve as high stringency recognition sequences for subsequent rounds of amplification. As a result, the annealing efficiency of different primers and their targets in a multiplex amplification or reaction is normalised, thereby reducing preferential amplification of certain targets. The chimeric primer comprise a 5' universal domain and a 3' target-specific domain. They are used for the simultaneous pcR amplification of multiple DNA targets in a sample. The primer containing AAT4744 is particularly useful in high-throughput genetic screening for mutations in genes like the CFTR, the Wilms Tumour, and the beta-

멾

Canalicular multispecific organic anion transporter protein; cMOAT protein; ATP-binding cassette transporter family; ABC transporter; Forward PCR primer used to amplify a 241 bp fragmnet of CMOAT CDNA

canaldualar multispecific organic anion transporter (CMOAT) protein CDNA.
The PCR product was cloned, and subsequently used in a RNAse protection assay. CMOAT is a new member of the ATP-binding cassette (ABC) transporter family. The ATP dependent CMOAT transporter system mediates transporter family. The ATP dependent CMOAT transporter system mediates comported family. The ATP dependent CMOAT transporter system mediates transporter family. The ATP dependent CMOAT protein. The mucleic acids are used to provide cells with CMOAT protein. The mucleic acids are used to provide cells with CMOAT protein activity, CMOAT protein.

Care used to provide cells with CMOAT protein activity, CMOAT protein activity in cells can be enhanced by increasing the level of glutathione, glucuromide and/or sulphate. Antisense constructs, especially derived from another multidary resistance (MDA) related protein, e.g. MDAP-1, to the mucleic acids and vectors can be used to decrease the level of cMOAT in a cell. The mucleic acids and proteins can be used especially in change of Dubin-Ohnson disease, Rotor disease or another disease involving cMOAT. The CMOAT gene may also be used as a selectable marker gene. (Updated on 25-MAR-2003 to correct PI field.) hepatobiliary excretion; multidrug resistance-associated protein; CMOAT protein activity; multidrug resistance-related protein; MDR-1; Dubin-Johnson disease; Rotor disease; PCR primer; ss. DNA encoding human and rat canalicular multispecific organic anion transporter proteins - useful for diagnosis and treatment of Dubin-Johnson disease and Rotor disease. ä Borst P, Sequence 20 BP; 4 A; 6 C; 3 G; 7 T; 0 U; 0 Other; Bosma PJ, (INTR-) INTROGENE BV. The MTS gene is useful in the diagnosis and prognosis of human cancer, e.g. by standard nucleic hybridisation techniques, of patient samples. The mutated sequences are those that are present in somatic mutations of the gene in cancers. The vectors can be used for gene therapy strategies to replace construct protein in patients. These can also be used to the expression constructs also for therapeutic strategies. In addition the expression constructs can also be used to some the expression constructs can also be used to my. Recombinant MTS can be used to screen for drugs to be used for cancer therapy, and the protein itself may also be used to restore MTS
                                                                                                                                                                                                                                                                                                                 Nucleic acids based on multiple tumour suppressor, MTS, sequences - useful as hybridisation probes, primers and recombinant production of MTS in the diagnosis and treatment of cancers related to MTS mutation(s).
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Unmethylated CpG dinucleotide, immune response, bacterial meningitis, nacural, killer cell activation; NK cell; Th2 response; neonatal sepsis, pulmonary disorder; asthma; environmentally induced airway disease; bacterial infection; endocoxemia; therapy; cystic fibrosis; inflammatory bowel disease; ss.

```
This sequence represents an unmethylated CpG dinuclectide, and can be used in the method of the invention. The method is for treating a subject having, or at risk of having an acute decrement in air flow, comprising administering a nucleic acid sequence containing at least one administering a nucleic acid sequence containing at least one unmethylated CpG. The nucleic acids containing an unmethylated CpG this nucleic acids containing an unmethylated CpG thin the nucleic acids containing an unmethylated CpG thin cells (NK) or redirecting a subject s immune response from a Thic or Thi response by inducing monocytic and other cells to produce Thi cytokines. They can be used to treat pulmonary disorders having an immunologic component, such as asthma or environmentally induced airway positive bacterial infections or endotoxeemia including bacterial meningitis, neonatal sepsis, cystic fibrosis, inflammatory bowel disease and liver citrhosis, gram-negative abdominal abserces has mentalled to the preumonia, gram-negative abdominal
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    PCR primer; amplification; yeast; UAS; upstream activating sequence; UAS; transcription terminator; call cycle; Upstream Activation Sequence; UAS; promoter; phosphorylation; cyclin; cyclin-dependent kinase; CDK; vector; cyclin kinase inhibitor; CKI; growth; wound healing; cancer therapy; ss.

AAV69949 to AAV69977 represent antisense oligonucleotides which are specifically hybridisable with a region of a nucleic acid encoding human For the antisense compound regalates the expression of the coligonucleotides which regulate the c-Jun protein. The present invention also describes antisense oligonucleotides which regulate the c-Jun protein. The antisense oligonucleotides are used for the diagnosis and treatment of diseases or disoraciers associated with Activating Protein 1 expression, of which c-Fos and c-Jun are subunits. The antisense oligonucleotides are used in compositions as c-Fos and/or c-Jun together with a carrier and a chemotherapeutic agent. They are used to regulate the expression of c-Fos or c-Jun in cells or tissues, preferably by inhibiting metastasis. They also regulate cell cycle expression and can be used to treat an animal
                                                                                                     Antisense oligonucleotides regulating Activating Protein 1 subunits - hybridise with c-fos and c-jun mRNA, used for regulating metastasis, cell cycle expression and hyperproliferative disease.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    DNA specific for Multiple Tumour Suppressor 1E1-beta gene - are useful for the diagnosis of cancers related to MTS1E1-beta mutation(s) and their treatment.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  MTS1; MTS1E1-beta; multiple tumour suppressor; diagnosis; cancer; germ-line mutation; familial melanoma locus; MLM; predisposition; ss.

                                                                                                                                                                                                                                                                                                       brimers AAV60731-V60732 were used to PCR amplify codous 1-149 of the human cyclin-dependent kinase 2 (hCDX2) gene. The amplified product was used to generate a fusion protein comprising part of the hCDX2 sequence linked to codons 154.302 of the yeast PH085 gene. The fusion protein is used to codons 154.302 of the yeast PH085 gene. The fusion protein is used to screen for compounds that affect mammalian cell cycle regulatory proteins. The method comprises administering a compound to a cell line, which contains a reporter gene linked to an Upstream Activation Sequence (UAS) and a promoter, where the UAS binds a transcription control factor (UAS) and a promoter, where the UAS binds a transcription control factor (TCF) which is regulated through cyclin/cyclin-dependent kinase (CDK) phosphorylation. Also included in the construct is an effector gene providing a gene product to permit normal cyclin/CDK regulation of the TCF. Expression of the reporter gene is then analysed in the cell line, thereby determining whether the compound affects the normal regulation. The method can be used to identify inhibitors and activators of mammalian cell cycle regulatory proteins, especially inhibitors and activators of cyclin/CDK/CKI complexes. The identified agents can be used for stimulating growth of cells (as in wound healing), or regulating excessive cell growth and division (as in cancer therapy)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      antisense oligonucleotide, phosphorothioate, regulation,

                                    Primers AAV11260-V11266 are used in the isolation of the human multiple tunmour suppression proteins, MTS1 and MTS1B1-beta. The MTS gene locus is also referred to as the familial melanoma (MLM) gene locus, located on human chromosome 9921. Germ line mutations in MTS genes can be used in the diagnosis of predisposition to cancers, e.g. melanoma, leukaemia, astrocytoma, gliboblastoma, lymphoma, glioma, Hodgkin's lymphoma, CLL, and cancers of the pancreas, breast, thyroid, ovary, uterus, testis, kidney, stomach and rectum
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     The invention provides a new method for identifying and characterising cells. The method for determining the genetic proximity of a first cell and a second cell comprises: (a) obtaining the first cell and the second cell (b) determining in the first cell and the second cell the pattern of expression of genes in a selected gene family; and (c) calculating a proximity index using a specified formula. The methods can be used for characterising cells, e.g. for determining the origin of a cell, its genetic status, whether it carries a genetic defect, or whether it is transformed. They can be used for detecting a selected genetic defect in an individual, e.g. a fetus. They can also be used for determining the effect of a selected treatment on a test cell. They can also be used for determining the effect of a selected treatment on a test cell. They can also be used for obtaining cells capable of expressing an homeobox related desired
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Identifying and characterizing cells by comparing the pattern of gene expression in a selected gene family.
                                                                                                                                                                                                                                                                                                      ö

The invention provides a new method for identifying and characterising cells. The method for determining the genetic proximity of a first cell and a second cell comprises: (a) obtaining the first cell and the second cell; (b) determining in the first cell and the second cell; (b) determining in the first cell and the second cell; (c) determining in a selected gene family; and (c) calculating a performed and the methods can be used for characterising cells, e.g. for determining the origin of a cell, its genetic status, whether it carries a genetic defect, or whether it is transformed. They can be used for determining the cite of a selected treatment on a test cell. They can also be used for determining the effect of a selected treatment on a test cell. They can also be used for obtaining cells capable of expressing an homeobox related desired containing the pattern of gene expression in a selected genetic miling the pattern of gene expression in a selected gene family. Sequences AAZ17803-Z18342 represent primers that can be used
                                                                                                                                                                                                                                        ö
property. The method uses reverse transcriptase polymerase chain reaction (RT-PCR) for determining the pattern of gene expression in a selected gene family. Sequences AA217803-218342 represent primers that can be used in the RT-PCR reactions to determine the pattern of gene expression. The gene family can be selected from a set of homeobox genes, kinase genes, protein phosphatase genes, P450 enzyme genes, steroid receptor superfamily genes or cadherin superfamily genes
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  Genetic proximity; gene expression; cell characterisation; homeobox gene; genetic defect; reverse transcriptase polymerase chain reaction; RT-PCR; kinase gene; protein phosphatase; P450; steroid receptor; cadherin;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Identifying and characterizing cells by comparing the pattern of gene expression in a selected gene family.

superfamily genes or cadherin superfamily genes

```
The invention provides a new method for identifying and characterising cells. The method for determining the genetic proximity of a first cell and the second cells. The method cell comprises: (a) obtaining the first cell and the second cell; (b) determining in the first cell and the second cell; (b) determining in the first cell and the second cell; (c) determining a specified formula. The methods can be used for proximity index using a specified formula. The methods can be used for characterising cells, e.g. for determining the origin of a cell, its genetic status, whether it carries a genetic defect, or whether it is transformed. They can be used for determining the original cells capable of expressing an homeobox related dealired of containing cells capable of expressing an homeobox related dealired containing cells capable of expressing an homeobox related dealired geneting. Sequences AALT1803-Z18342 represent primers that can be used for the family. Sequences AALT1803-Z18342 represent primers that can be used in the RT-PCR reactions to determine the pattern of gene expression. The gene family can be selected from a set of homeobox genes, kinase genes, protein phosphatase genes, P450 enzyme genes, steroid receptor
                                                                                                                                                                        ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            Genetic proximity, gene expression; cell characterisation; homeobox gene; genetic defect; reverse transcriptase polymerase chain reaction; RT-FCR; kinase gene; protein phosphatase; P450; steroid receptor; cadherin;
in the RT-PCR reactions to determine the pattern of gene expression. The gene family can be selected from a set of homeobox genes, kinase genes, protein phosphatase genes, P450 enzyme genes, steroid receptor superfamily genes
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Identifying and characterizing cells by comparing the pattern of gene expression in a selected gene family.

Another primer pair (see AAZ20165, AAZ20185-86) was used to amplify a poorly conserved 536 bp fragment of AAZ20185-86) was used to amplify a poorly conserved 536 bp fragment of AAZ20181, AAZ20181). The amplified fragments were used as probes in experiments to demonstrate that certain PAGs, including bovine PAG4, 5, and in the syncytium formed between trophectoderm and uterine epithelium. Such PAGs are useful in immunoassays of the invention for the early

                                                                                                                                                                                                                                                                                                                              Oligonucleotides targeted to human raf mRNA useful for treating and diagnosing abnormal proliferative states and inhibiting raf expression.
                                                                                                                                                                                                                                                                                                                                                                                  The invention provides antisense oligonucleotides targeted to mRNA encoding human raf and capable of inhibiting raf expression. The antisense oligonucleotides are useful for treating and diagnosing abnormal proliferative scates and hyperproliferation (e.g. cancer, psoritasis, or blood vessel restences), and inhibiting raf expression. Sequences AAZ11511-537 and AAZ11555-573 represent antisense oligonucleotides for human c-raf kinase

Cells expressing the new receptor abunits are useful for identifying GABARR agonists and antagonists. HG20 proteins and their antagonists are useful for inhibiting HG20 or GABARR function, useful for treating depression, eighlepsy, neuropsychiatric disorders. Generalism subscular contractions, and central nervous system disorders. The present sequence represents a PCR primer for human HG20, which is used in the exemplification of the
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Human, iPFK-2; cancer malignancy diagnostic assay; inflammatory disease;

invention relates to a cancer malignancy diagnostic assay for determining the presence of inducible phosphoffunctokinase-2 (ippr-2) specific sequences in a sample of a body or tumour fluid or tissue. The assay comprises obtaining a sample of a body or tumour fluid or tissue and performing a sequence identity assay to look for the presence of ippr-2 specific sequences. The method is useful for diagnosis of malignant orancer by detecting the presence of iPFK-2 specific sequences. Antisense iPFK-2 injouncebotides are useful for treatment of cancer and inflammatory disease. Antagonists of iPFK-2, such as an iPFK-2 enzyme inhibitor or anti-iPFK-2 antibody are also useful for treatment of cancer
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Human; iPFK-2; cancer malignancy diagnostic assay; inflammatory disease; inducible phosphofructokinase-2; tumour; malignant cancer; diagnosis;
                                                                                                                                    This sequence represents a human iPFK-2 antisense oligonucleotide. The
                                                Cancer malignancy diagnostic assay useful for diagnosis of malignant cancer and, in treatment of cancer and inflammatory disease.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Cancer malignancy diagnostic assay useful for diagnosis of malignant cancer and, in treatment of cancer and inflammatory disease.
                                                                                                                                                                                                                                                                                                                                                                                                                                 .

sequences in a sample of a body or tumour fluid or tissue. The assay comprises obtaining a sample of a body or tumour fluid or tissue and performing a sequence identity assay to look for the presence of iPFK-2 specific sequences. The method is useful for diagnosis of malignant cancer by detecting the presence of iPFK-2 specific sequences. Antisense inflammatory disease. Antagonists of iPFK-2, such as an iPFK-2 enzyme inflammatory disease. Antagonists of iPFK-2, such as an iPFK-2 enzyme and inflammatory disease
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      AAV74237-V74253 are oligodeoxynucleotide (ODN) primers used to describe a method for enhancing the immunostimulatory effect of an antigen encoded involves determining the cpd-N and Cpd-S motife present in the construct. The method involves determining the Cpd-N and Cpd-S motife present in the construct, removing neutralising CpG (Cpd-N) motife and optionally inserting attimulatory CpG (Cpd-S) motife in the construct, thereby producing a nucleic acid construct having enhanced immunostimulatory efficacy. The method can be used for immunisation against viral antigens, e.g. from hepatitis B virus (HBV), bacterial antigens or an antigen derived from a parasite. They can also be used for expression of a therapeutic polypeptide, e.g. growth factors, toxins, tumour suppressors, cytokines,
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               CpG-N motif; immunostimulation; antigen; CpG-S motif; immunisation; ODN; viral antigen; bacterial antigen; parasite; therapeutic; growth factor; toxin; tumour suppressor; cytokine; apoptotic protein; interferon; hormone; clotting factor; liqand; receptor; oligodeoxynucleotide; se.

```
Oligonuclectides AAV70607-11 were used to isolate nucleic acid encoding a murine multiple tumour suppressor IEI-beta (WTSIEI-beta) protein. Primers designed from the gene can be used to design primers to detect abnormalities i.e. polymorphisms which may predispose towards malignancies such as melanoma, leukaemia, astrocytoma, lymphoma, glioma, as well as tumours of e.g. the breast, thyroid, pancreas, uterus and kidneys. (Updated on 20-MAR-2003 to correct PR field.) (Updated on 20-MAR-2003 to correct PR field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Vaccine; eye disease; conventional trachoma; nonendemic trachoma; paratrachoma; inclusion conjunctivitis; genital disease; perihepatitis; nongonococcal uretritis; epidymitis; cervicitis; salpingitis; PCR primer; bartholinitis; pneumopathy; venereal lymphogranulomatosis; ss.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         AAV74293-V74297 are antisense oligonuclectide primers used against the intercellular adhesion molecule ICMV-1 for preventing perfusion injury during transplantation. The oligonuclectides are used for pre-operative treatment of the transplant donor or for pre-treatment of the donor organ (preferably kidney, heart, lung or pancreas) before transplantation

These ORFs encode polypeptides (see AAY36754-Y37949) which can be used as vaccines against Chlamydia trachomatis. Antisense and ribozyme sequences can also be used to control growth of the microorganism. Chlamydia trachomatis is responsible for a large number of diseases, e.g. eye diseases auch as conventional trachoma, nonendemic trachoma, paratrachoma, and inclusion epidymitis, cervicitis, aplingitis, perihepatitis, bartholinitis; preumopathy in breast feeding infants; and venereal lymphogranulomatosis. The polypeptides of the invention may be of use in treating these

Genome sequence of Chlamydia trachomatis.

```
PCR primers AAZ01426-Z06209 were used to amplify open reading frames choose polypeptides (see AAY36754-Y37949) which can be used as vaccines against Chlamydia trachomatis. Antisense and ribozyme sequences can also be used to control growth of the microorganism. Chlamydia trachomatis is responsible for a large number of diseases, e.g. eye diseases such as conventional trachom, nonendemic trachoma, paratrachoma, and inclusion conjunctivitis; genital diseases such as nongonococcal uretritis, practicis, genital diseases such as nongonococcal uretritis, prehompathy in breast feeding infants; and venereal lymphogramulomatosis. The polypeptides of the invention may be of use in treating these
                                                                                                                                                                                                                                                                                                                                                                                                                                 Gaps

Genome sequence of Chlamydia trachomatis. Disclosure; Page 1802; 1755pp; English

WPI; 1999-371125/31.

PCR primers AAZ01426-206209 were used to amplify open reading frames (OREs) of the genome of Chlamydia trachomatis (see AAZ01425). These ORFs encode polypeptides (see AAY36754.737949) which can be used as vaccines against Chlamydia trachomatis. Antisense and ribozyme sequences can also be used to control growth of the microorganism. Chlamydia trachomatis is responsible for a large number of diseases, eg. eye diseases such as conventional trachoma, nonendemic trachoma, paratrachoma, and inclusion conjunctivitis; genital diseases such as nongonococcal uretritis,

This oligonuclectide represents an antisense oligonuclectides (ASO) targeted to a region in the intercellular adhesion molecule (ICAM)-1 genewhich is generated by a method of selectively ranking mucleic acid molecules for inhibitory efficiency. The method comprises: (a) determining the fraction of each of a set of 13 nearest-neighbour nucleic acid base pair types in a target sequence zone RNA.ASO-DNA hybrid nucleic acid base pair types in a target sequence zone RNA.ASO-DNA hybrid nucleic fractions into formulas to determine the fractions of each of a series of 13 nearest-neighbour nucleic acid base pair types to provide determined fractions, and (c) multiplying the fractions of the 13 nearest-neighbour nucleic acid base pair types by a stability ranking to the nucleic acid antisense sequence; where the results are ordered to produce a ranking. The process is used to rank nucleic acid sequences based on the stability
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Selectively ranking nucleic acid molecules, for inhibitory efficiency comprises determining the fraction a set of nearest-neighbour nucleic acid base pair types in a target sequence zone, substituting nearest-neighbour nucleic acid base pair fractions to determine the fractions and
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  nucleic acid oligomer binding interactions to select sequence zones
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    Gaps

CER primers AAZ10708-33 were used to amplify exons I to 11 of human HKNGI

(Hong Kong new gene 1). HKNGI is a gene associated with bipolar affective
disorder (BAD). HKGNI polymucleotides are useful to identify compounds

modulating HKNGI gene expression or HKNGI polymeptide expression/
activity. Compounds inhibiting or enhancing HKNGI gene expression or
activity. Compounds inhibiting or enhancing HKNGI gene expression or
activity in individuals can then be administered therapeuticially to treat
HKNGI-mediated disorders, especially neuropsychiatric disorders e.g. BAD,
schizophrenia, or HKNGI-mediated myopia disorders, such as early-onset
contropic of HKNGI-mediated myopia disorders is uch as early-onset
contropic to identify individuals having, or at risk of developing, HKNGI
chagnosis to identify individuals having, or at risk of developing, HKNGI
confediated disorders due to mutations in the HKNGI gene. Such mutations
confediated by result in the production of a protein with a different
sequence to the human full-length HKNGI polypeptide or splice variant
sequence to the human full-length HKNGI polypeptide or splice variant
sequence to the human full-length HKNGI polypeptide or splice variant
sequences, especially the substitution of a lysine for a glutemic acid at
confediated special substitution of a lysine for a glutemic acid at
to produce probes or primers to identify similar sequences (e.g. mutants
confediated sequences from different species) and to produce transgenic animals
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Human; alpha-7 nicotinic receptor; neuronal; hybridisation; probe;

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  primers AAX21344-X21345 were used to PCR amplify a 375 bp fragment of the apolipoprotein E gene. The invention relates to the diagnosis of Alzheimer's disease (AD) by detecting one or murations, in the genomic region that regulates expression of the apolipoprotein E (apo E) that results in: (a) altered sene expression relative to a control population, or (b) altered relative expression relative to a control Alternatively AD is detected by determining the levels of apo E. Alternatively AD is detected by determining the levels of epsilon-2, -3 or -4 alleles or mutations in the Thi/E470s sequence (a polymorphism in the promotter region). The T allele of Thi/E470s is associated with increased risk of AD (independently of the effect of the epsilon allele) and increases the risk associated with epsilon 4 in epsilon
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Diagnosing Alzheimer's disease - by detecting mutations in the regulatory region of the apo E gene, or levels of apo E allele expression.

The present invention describes an isolated nucleotide sequence (I) encoding at least a portion of the human alpha-7 neuronal nicotinic acceptor (alpha7-hnAchR). Also described are: (I) a peptide encoded by (I); (2) a vector comprising (I); (3) a host cell transformed with a vector of (2); (4) a polymucleotide comprising at least 15 nucleotides which hybridises under stringent conditions to at least a portion of (I); (3) a method for detection of a polymucleotide encoding alpha 7-hnAchR in a biological sample; and (6) a method for amplification of an of nucleic acid from a sample suspected of containing nucleic acid contains and probes from the present encoding alpha 7-hnAchR. The primers and probes from the present condition can be used on brain tissue and blood samples of humans suspected of suffering from schizophrenia, small cell lung carcinoma, breast cancer and nicotine-dependent illness. This is particularly useful condidiagnosed are epilepsy (e.g. juvenile myoclonic epilepsy) and prader-Willi and Angelman's syndromes
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     ô
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Tumour necrosis factor alpha; TNF-alpha; antisense oligonucleotide; ASO; inhibition; expresssion; treatment; disease; disorder; ss.

Antisense oligonuclectides (ASO) for inhibiting a tumour necrosis factoralpha (TNP-alpha) gene in an animal, preferably a human, comprise 12-50 nucleotides, 90% of which are complementary to a region of mENA containing a GGGA sequence motif. The ASO is used to inhibit expression of a gene in an animal and for treating the animal when afflicted with a fisaeae or disorder characterised by the presence of an mRNA from a gene containing a GGGA motif. The ASO are specifically targeted to a GGGA sequence motif found in mRNA from a gene. A study of known ASO has shown that at least half of the most effications ASO's contain one or more TCC motifs. This ASO comprises a TCCC motif followed by a cytosine residue and corresponds to a region of the human ICAM-1 3' untranslated region
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Respiratory disease; pneumonia; bronchitis; heart disease; sarcoidosis; sinusitis; purulent otitis media; erythema nodosum; pharyngitis; vaccine; neutralising epitope; PCR primer; ss.

AAX91991-X97517 represent PCR primers used to amplify open reading frames and other nucleic acid sequences from the genome of Chlamydia pneumoniae (see AAX91990). C. pneumoniae causes respiratory disease such as pneumonia and bronchitis and is thought to be a contributing factor in heart disease, sarcoidosis, sinusitis, purulent otitis media, erythema nodosum or pharyngitis. The polypeptides encoded by the open reading frames of the C. pneumoniae genome (see AAX34564-AAX35879) can be used in immunogenic compositions as vaccines. Vectors containing C. pneumoniae mucleotides sequences can also be used as immunogenic compositions, especially where the vector directs the expression of a neutralising epitope of C. pneumoniae
                                            AAX91991-X97517 represent PCR primers used to amplify open reading frames and other nucleic acid sequences from the genome of Chlamydia pneumoniae present of Chlamydia pneumoniae present of Chlamydia pneumoniae present of Chlamydia pneumoniae present of sease such as pereumonia and bronchitis and is thought to be a contributing factor in heart disease, sarcoidosis, sinusitis, purulent otitis media, erythema rodosum or pharyngitis. The polypeptides encoded by the open reading frames of the C. pneumoniae genome (see AAX14584-AAX15879) can be used in immunogenic compositions as vaccines. Vectors containing C. pneumoniae especially where the vector directs the expression of a neutralising epitope of C. pneumoniae
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Respiratory disease; pneumonia; bronchitis; heart disease; sarcoidosis; sinusitis; purulent otitis media; erythema nodosum; pharyngitis; vaccine; neutralising epitope; PCR primer; ss.
                                                                                                                                                                                                                                                                                                               0.8%; Score 13.6; DB 1; Length 20;

C. preumoniae causes respiratory disease such as pneumonia and bronchitis and is thought to be a contributing factor in heart disease, sarcoidosis, sinusitis, purulent ocitis media, erythema nodosum or pharyngitis. The polypeptides encoded by the open reading frames of the C. pneumoniae genome (see AAX34584- AAX35879) can be used in immunogenic compositions as vaccines. Vectors containing C. pneumoniae especially where the vector directs the expression of a neutralising epitope of C. pneumoniae

AAX91991-X97517 represent PCR primers used to amplify open reading frames and other nucleic acid sequences from the genome of Chlamydia pneumoniae (See AAX91990). C. pneumoniae causes respiratory disease such as pneumonia and bronchitis and is thought to be a contributing factor in heart disease, sarcoidosis, sinusitis, purulent citis media, erythema nodosum or pharyngitis. The polypeptides encoded by the open reading frames of the C. pneumoniae genome (see AAX34584- AAX35879) can be used in immunogenic compositions as vaccines. Vectors containing C. pneumoniae especially where the vector directs the expression of a neutralising epitope of C. pneumoniae
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Respiratory disease; pneumonia; bronchitis; heart disease; sarcoidosis; sinusitis; purulent otitis media; erythema nodosum; pharyngitis; vaccine; neutralising epitope; PCR primer; ss.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   AAX91991-X97517 represent PCR primers used to amplify open reading frames and other nucleic acid sequences from the genome of Chlamydia pneumoniae (see AAX91990). C. pneumoniae causes respiratory disease such as pneumonia and bronchitis and is thought to be a contributing factor in heart disease, sarcoidosis, sinusitis, purulent otitis media, erythema nodosum or pharyngitis. The polypeptides encoded by the open reading frames of the C. pneumoniae genome (see AR34584-AAX35879) can be used in immunogenic compositions as vaccines. Vectors containing C. pneumoniae en also be used as immunogenic compositions, especially where the vector directs the expression of a neutralising
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Respiratory disease; pneumonia; bronchitis; heart disease; sarcoidosis;

AAX91991-X97517 represent PCR primers used to amplify open reading frames and other nucleic acid sequences from the genome of Chlamydia pneumoniae (see AAX91990). C. pneumoniae causes respiratory disease such as pneumonia and bronchitis and is thought to be a contributing factor in heart disease, sarcoidosis, sinusitis, purulent otitis media, erythema nodosum or pharyngitis. The polypeptides encoded by the open reading frames of the C. pneumoniae genome (see AAX34584- AAX35879) can be used in immunogenic compositions as vaccines. Vectors containing C. pneumoniae especially where the vector directs the expression of a neutralising
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                AAX91991-X97517 represent PCR primers used to amplify open reading frames and other nucleic acid sequences from the genome of Chlamydia pneumoniae (see AAX91990).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     New nucleic acid molecule encoding a biologically active DKR polypeptide, useful in treatment of cancer, e.g. mammary tumors and stem cell tumors.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                AAA08849-60 are oligonucleotide primers and adaptors used in cloning the murine DKR-3 gene (AAA08838). The murine DKR-3 open reading frame has bomology to human rig-11ke 7-1 murine DKR-3 open reading frame has elest 4 gene. DKR-1 is a human ortholog of dkk-1 (dickkopf-1), a novel gene identified in Kenopus and mouse, purportedly an arragonist of wnt-8 pattern. DKR-2, -3 and -4 are each related to DKR-1 by their cysteine pattern. DKR-1; a lao involved in morphogenesis in the developing embryo, and therefore a growth factor. By inference DKR polypeptides are also growth factors. The DKR polypeptides are useful for treating cancer, e.g. mammary tumors, stem cell tumors, or other cancers in which the wnt and/or soulc hedgehog (shh) signal transduction pathways are activated. They can also be used to enhance tissue differentiation, such as bone formation and hematopoietic cell formation
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         DKR-3; human rig-like 7-1 mRNA; chicken lens fiber protein; clfest 4; dkk-1; dickkopf-1; antagonist; wnt-8 signaling; morphogenesis; primer; growth factor; cytostatic; sonic hedgehog; tissue differentiation; ss.
nucleotides sequences can also be used as immunogenic compositions, especially where the vector directs the expression of a neutralising epitope of C. pneumoniae {\bf p}
                                                                                                                                                                 Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Gaps

```
The invention relates to the isolation of the gene encoding the human multiple tumour suppressor 1 (MTS1) (AAA95633). The MTS1 protein has a cytostatic activity and is used in protein replacement therapy. This sequence is a PCR primer used to isolate the mouse pl6 gene (a homologue of the MTS1 gene). MTS1 is useful in diagnosing human cancers such as (ocular) melanoma, leukemia, astrocytoma, glioblastoma, lymphoma, glioma, Hodgkin's lymphoma, multiple myeloma, sarcoma, myosarcoma, cholangiocarcinoma, squamous cell carcinoma, CLL, and cancers of pancreas, breast, stomach, brain, proteter, bladder, thyroid, ovary, uterus, testis, kidney, colon and rectum. The MTS1 gene and protein is useful in gene therapy, protein replacement therapy and protein mimetic
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Novel protein composition useful in protein replacement therapy for diagnosing and treating cancer comprises a specific weight percent of human multiple tumor suppressor I polypeptide.
                                                                                                                                                             Cytostatic; human; multiple tumour suppressor 2; MTS2; diagnostic; cancer; gene therapy; protein replacement therapy; ss; mouse.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     . The present invention describes oligonuclectides containing bioreversible phosphate ester groups and their mimetics. The oligonuclectides are of value in therapeutics, diagnostics, and as research reagence. The compound from the present invention may be used in control of hereditary, metabolic, and/or cellular processes in any organism utilising DNA-RNA cranscription and/or RNA-protein translation. These organisms include prokaryotic undelular and multicellular organisms; including bacteria, yeasts, protozoa, algae, and all plants and higher animal forms, including warm blooded animals, particularly unans, also corganelle sub-cellular translation and transcription processes. The new synthetic process provides pro-oligonucleotides, i.e., oligonucleotides blocked at phosphate groups by bioreversible groups which can be cleaved by intracellular and intercellular and drugs. By careful selection of protecting groups, deprotection of mucleobases and partial deprotection of protecting groups, deprotection of mucleobases and partial deprotection of specific groups include s-pivaloylmercaphocethy! (SBMS) and complete sub-oligonal process and partial deprotection cyanocthylcarbony! (CEOC) groups. Spacer molecules include diglycoly!

CCCCH_ZOCH_ZOCH_ZOC) and its analogue with a catechol biresidue replacing the cyanom and its analogue with a catechol biresidue replacing the cyanom timent invaries and biosphoteto acid). The present sequence
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 ö

Peroxisome proliferators are agents that induce peroxisomal proliferation. Peroxisome proliferator-activated receptors (PPARS) are members of the steroid receptor superfamily, and are ligand-activated transcription factors. There are three mammalian subtypes of PPAR, alpha, beta (also known as delta) and gamma. The present invention relates to inhibiting angiogenesis by contacting PPAR gamma with a PPAR gamma characterised by excessive neovascularisation e.g. rheumatoid arthritis, psoriasis, atheroselerosis, diabetes, retinopathy, retrolental fibroplasia, neovascular glaucoma, age-related macular degeneration, transplantation, chronic inflammation, und inflammation, endometriosis and obesity. The present sequence is a PCR primer for human PPARbeta gene. The resulting PCR product was used in the analysis of PPARbeta
                                                                                                         neovascularisation; tumour growth; metastasis; rheumatoid arthritis; psoriasis; atherosclerosis; diabetes; retinopathy; PPAR; Human; retrolental fibroplasis; age-related macular degeneration; neovascular glaucoma; hemanda, thyroid hyperplasis; Grave's disease; inflammatiobesity; transplantation; transcription factor; PCR primer; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Endocrine disruptor; dioxins; organic halocarbon; phenol; agrochemical; phthalate esters; aromatic hydrocarbon; organotin compound; oestrogen;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Inhibiting angiogenesis comprises administration of PPAR gamma ligands for treating tumors, neovascularization and rheumatoid arthritis.
                                                                                       Peroxisome proliferator activated receptor; angiogenesis inhibition

```
disruptor is new and comprises isolation of mRNA from cells, tissue or organized must be endocrine disruptor, and hybridising with a DNA array contact with the endocrine disruptor, and hybridising it with a DNA array containing immobilized gene fragments from genes which may be affected by the endocrine disruptor. The results of the hybridisation are then compared with a compariation sample to of the hybridisation are then compared with a compariation sample to detect genes whose expression is altered by endocrine disruptors such as altered panes whose expression is altered by endocrine disruptors such as disruptor incompounds, ocstrogens, mylex, toxaphene, aldicarb and kepones. The types of genes whose expression may toxaphene, aldicarb and kepones. The types of genes whose expression may be altered by these disruptors include those involved in nuclear receptor transcriptional coupling, kinase type signal transduction, gonad differentiation, receptor type kinases, intermediate filament markers, apportosis, DNA damage response, repair and recombination, receptors, cell cycle and growth regulators, cell adhesion, motility and invasion, angiogenesis regulation, invasion regulation, cell-cell interaction, RNO family small GTPase regulation and growth factors and cytchines.

Completed sequences of genes which may be affected by an endocrine
            nuclear receptor transcriptional coupling; gonad differentiation, intermediate filament marker; cell cycle; growth; regulation; oncogene; tumour suppressor; apoptosis; DNA damage response; cell adhesion; motility; angiogenesis regulation; invasion regulation; growth factor; cytokine; primer; 88.
                                                                                                                                                                                                                                                                                                                                                                                                                                             mRNA from calls exposed to an endocrine disruptor is hybridized with a DNA array of gene fragments for detection of genes whose expression is altered by the endocrine disruptor.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Gaps

This sequence is a PCR primer for DNA encoding mouse beta, protein which is homologous to the human MYSIBlbera protein. The invention relates to a method for diagnosing a polymorphism associated with a predisposition to cancer by detecting a germ-line alteration of a wild-type Multiple Tumour Suppressor (MYS) gene or its expression products in a human sample. The method comprises detecting a germ-line alteration of a wild-type MXS gene or its expression products in a human sample, the alteration indicating a predisposition to at least one of the cancers. The cancer is selected from melanoma, leukaemia, astrocytoma, glioblastoma, lymphoma, glioma, Hodgkin's lymphoma, chronic lymphocytic leukaemia (CLL), and cancers of the pancreas. Dreast, thyroid, ovary, uterus, testis, kidhey, stomach and rectum. The method may be used as the basis for developing very important diagnostic tests capable of predicting the predisposition to cancer. The MYS gene is involved in the progression of multiple tumour types and may provide means for a general anti-cancer therapy by virtue of its ability to suppress tumour growth
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          ó

This sequence represents a PCR primer for the human multiple tumour suppressor IEIbeta (MTSIEIbeta) coding sequence. The invention relates to the human MTS2 DNA and protein sequences. The DNA sequences are useful to diagnosing or determining a predisposition to cancers e.g. melanoma, leukaemia, lymphoma, glioma, Hoddxin's lymphoma and cancers of the pancreas, breast, thyroid, ovary, kidney, uterus and stomach
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       DBL gene; Duffy-binding like gene; ebl-1; Duffy Antigen Binding Protein; DABP; Sialic Acid Binding Protein; SABP; malaria; vaccine; immunisation; protozoacide; eba-175; PCR primer; 88.
